Part 1: Building a Foundation

What is the size of an `int` data type in C on a typical 32-bit system?

Hint: Consider the standard sizes of data types in C.

- 1 byte
- 2 bytes
- 4 bytes ✓
- 8 bytes

■ The size of an `int` data type on a typical 32-bit system is 4 bytes.

Which of the following are valid variable names in C?

Hint: Remember the rules for naming variables in C.

- `int`
- `2ndValue`
- `_result` ✓
- `totalSum` ✓

■ Valid variable names in C must start with a letter or underscore and can contain letters, digits, and underscores.

Explain the difference between declaring a variable and initializing a variable in C.

Hint: Think about the steps involved in using a variable.

Declaring a variable means specifying its type and name, while initializing a variable means assigning it a value.

List the four basic data types in C and provide a brief description of each.

Hint: Consider the fundamental types used in C programming.

1. What is int?

A data type used to store integer values.

2. What is float?

A data type used to store single-precision floating-point values.

3. What is char?

A data type used to store single characters.

4. What is double?

A data type used to store double-precision floating-point values.

The four basic data types in C are int (integer), float (floating-point), char (character), and double (double-precision floating-point).

Which operator is used to check equality between two variables in C?

Hint: Think about the operators used for comparison.

- =
- == ✓
- !=
- <>

The equality operator in C is `==`.

Part 2: Comprehension and Application

What is the output of the following code snippet? ``c int x = 5; if (x > 3) { printf("Hello"); } else { printf("World"); } ``

Hint: Consider the condition being evaluated in the if statement.

- Hello ✓
- World
- HelloWorld
- No output

The output of the code snippet will be 'Hello' because the condition $x > 3$ is true.

Describe how a `switch` statement differs from an `if-else` statement in C.

Hint: Think about the structure and use cases of each statement.

A `switch` statement is used for multiple discrete values of a variable, while `if-else` is used for evaluating conditions that can be true or false.

Provide examples of when you would use a `for` loop versus a `while` loop.

Hint: Consider the scenarios where each loop is most effective.

1. When to use a for loop?

When the number of iterations is known, such as iterating over an array.

2. When to use a while loop?

When the number of iterations is not known, such as reading input until a certain condition is met.

A `for` loop is typically used when the number of iterations is known, while a `while` loop is used when the number of iterations is not predetermined.

What is the return type of a function that does not return any value?

Hint: Think about the keyword used for functions that do not return a value.

- int
- void ✓
- float
- char

The return type of a function that does not return any value is `void`.

Write a simple C function that takes two integers as parameters and returns their sum.

Hint: Consider the syntax for defining a function in C.

A simple C function to return the sum of two integers can be defined as follows: `int sum(int a, int b) { return a + b; }`.

Part 3: Analysis, Evaluation, and Creation

What will be the output of the following code? `c int arr[] = {1, 2, 3, 4, 5}; printf("%d", *(arr + 2));`

Hint: Consider how array indexing works in C.

- 1
 2
 3 ✓
 4

The output of the code will be 3, as it accesses the third element of the array.

Analyze the relationship between arrays and pointers in C. How can pointers be used to manipulate array elements?

Hint: Think about how pointers can reference array locations.

Pointers can be used to access and manipulate array elements by pointing to the memory address of the first element of the array.

Which of the following are valid ways to access the third element of an array `arr` in C?

Hint: Consider the different methods of accessing array elements.

- `arr[2]` ✓
- `*(arr + 2)` ✓
- `arr[3]`
- `*(arr + 3)`

Valid ways to access the third element of an array `arr` are `arr[2]` and `*(arr + 2)`.

Design a structure in C to store information about a book, including title, author, and number of pages. Write a function to print the details of a book.

Hint: Think about the syntax for defining structures in C.

A structure for a book can be defined as follows: `struct Book { char title[100]; char author[100]; int pages; };` and a function can be written to print its details.

Which of the following are necessary steps to read from a file in C?

Hint: Consider the functions used for file operations.

- Open the file using `fopen()`. ✓
- Use `fscanf()` or `fgets()` to read data. ✓
- Close the file using `fclose()`. ✓
- Initialize the file pointer to `NULL`.

Necessary steps to read from a file in C include opening the file using `fopen()`, reading data with `fscanf()` or `fgets()`, and closing the file with `fclose()`.

Evaluate the pros and cons of using structures versus arrays for storing complex data in C.

Hint: Consider the differences in data organization and access.

Structures allow for grouping different data types together, while arrays are best for storing multiple items of the same type. Each has its own advantages depending on the use case.
